# PROVINCIAL AND REGIONAL LIFE TABLES

## TABLES PROVINCIALES ET RÉGIONALES DE MORTALITÉ

1960-1962

### INTRODUCTION

National life tables for the census years 1931, 1941, 1951, 1956 and 1961, have been previously published, based on the average annual number of deaths during the 3-year period around those years and the population counts provided by those national censuses.

In addition to national figures there has been an increasing demand and need for a measure of longevity differences between the several provinces and regions of the country. This publication therefore completes the comparable series of provincial and regional life tables for the same periods as the national tables. As in the past, separate tables are included in this report for the provinces of Quebec, Ontario and British Columbia while the 4 Atlantic and the 3 Prairie provinces are each combined as "regions". This system of grouping of data into regions is employed where the number of deaths and population of each age and sex in any individual province are so small, or the fluctuations in these — even over a 3-year period — are such that the accuracy of the computations might be affected.

The principal functions or terms and the formulae used in constructing these tables are identical to those used for the previously published "Canadian Life Tables, 1960-1962" (Catalogue No. 84-516). However for convenience of reference an explanation of the functions or terms used in these tables are repeated below:

- $l_x$  — the survivors of a cohort of 100,000 persons, i.e. the number of persons still alive at the beginning of each age;
- $d_x$  — the number of deaths in each age interval;
- $q_x$  — the probability of dying within a specified age interval for a person of a specified age  $x$ ;
- $p_x = (1 - q_x)$  i.e. the probability of surviving till the next age interval for a person who has attained age  $x$ ;
- $L_x$  — the aggregate number of life-years lived by the survivors of the cohort during each age interval, or, in the artificial population, the number of persons of age  $x$  at any given moment of the year;
- $T_x$  — the total number of years to be lived by persons of age  $x$  and older, or, in the artificial population, the total number of persons at age  $x$  and older;
- $e_x$  — the mean expectation of life, i.e. the average number of years of life remaining to those who have survived to age  $x$ , generally referred to simply as "life expectancy".

Nous avons déjà publié des tables canadiennes de mortalité en nous basant sur la moyenne annuelle des décès durant une période triennale encerclant les années de recensement 1931, 1941, 1951, 1956 et 1961, ainsi que sur les chiffres démographiques des mêmes années.

En plus d'une demande de chiffres de portée canadienne, il s'est fait sentir un besoin croissant d'une mesure des différences de longévité entre les diverses provinces ou régions. La présente publication complète donc les séries comparables des tables provinciales ou régionales de mortalité pour les périodes déjà couvertes par les tables canadiennes. Comme dans le passé, les tables du présent rapport paraissent séparément pour ce qui est du Québec, de l'Ontario et de la Colombie-Britannique et collectivement en ce qui touche et les quatre provinces atlantiques et les trois provinces des Prairies, groupes considérés comme régions. Ce groupement de données par régions sert quand le nombre de décès et la population de chaque âge et sexe, dans une province donnée, sont trop minimes ou quand les fluctuations, — même au cours d'une période triennale, — y sont telles que l'exactitude des calculs en puisse être affectée.

Les fonctions ou termes principaux et les formules dont on s'est servi pour établir ces tables sont identiques à ceux qu'ont antérieurement utilisés les "Tables canadiennes de mortalité, 1960-1962" (numero de catalogue 84-516). Toutefois, pour fins de référence, nous répétons plus bas l'explication des fonctions ou termes utilisés dans les tables:

- $l_x$  — les survivants d'une génération de 100,000 individus i.e. le nombre de personnes encore vivantes au début de chaque intervalle d'âge.
- $d_x$  — le nombre de décès à chaque intervalle d'âge.
- $q_x$  — la probabilité pour une personne d'un âge donné  $x$  de mourir dans un intervalle d'âge donné.
- $p_x = (1 - q_x)$  i.e. la probabilité pour une personne qui a atteint l'âge  $x$  de survivre jusqu'au prochain intervalle d'âge.
- $L_x$  — le nombre d'années vécues par tous les survivants de la génération à chaque intervalle d'âge, ou, dans la population artificielle, le nombre de personnes d'âge  $x$ , à un moment quelconque de l'année.
- $T_x$  — le nombre total d'années restant à vivre aux personnes d'âge  $x$  et plus, ou, dans la population artificielle, le nombre total de personnes d'âge  $x$  et plus.
- $e_x$  — l'espérance moyenne de vie i.e. le nombre moyen d'années restant à vivre à ceux qui ont survécu jusqu'à l'âge  $x$ ; on l'appelle généralement "Espérance de vie".
