INTRODUCTION

Methodological Note

A life table represents a universally accepted demographic or actuarial model which portrays in a clear and concise manner a synthesis of mortality experience of a population and permits one to derive comparative measures of expected longevity. In the construction of these tables, it is customary to assume that a hypothetical cohort of 100,000 individuals born at the same moment in time is subject to age-sex-specific mortality rates actually experienced by a population in a specified period of time.

The present report contains the tables generated on the basis of age-sex-specific mortality rates for Canada and the provinces prevailing in the period 1985-1987. For all the provinces except Prince Edward Island, the detailed tables by single years of age, for males and females as well as the tables for the sub-divisions of the first year of life, have been produced. With respect to Prince Edward Island, however, because of the smallness of the required frequencies involved, only abridged tables with five-year groupings have been produced.

Input Data

For the construction of these tables, the following data, separately for males and females and for Canada and provinces, were required as input:

Number of deaths by single years of age up to the age of four and five-year groupings for ages five and over for the calendar years 1985, 1986 and 1987.

The number of infant deaths by the sub-divisions of the first year of life for the years 1985, 1986 and 1987.

The number of deaths of children aged one to four, by year of birth, for the years 1985, 1986 and 1987.

Census population by single years of age as of June 1, 1986.

Note Méthodologique

La table de mortalité représente un modèle démographique ou actuariel universellement accepté qui constitue une synthèse claire et concise de la mortalité d'une population et permet de calculer des mesures comparatives de la longévité prévue. Lorsque l'on construit ces tables, on pose habituellement pour hypothèse qu'une cohorte fictive de 100,000 personnes nées au même moment affiche les mêmes taux de mortalité par âge et par sexe que la population pour une période déterminée.

La présente publication contient les tables dressées en fonction des taux de mortalité par âge et par sexe enregistrés pour le Canada et les provinces pendant la période 1985-1987. Pour toutes les provinces sauf l'Île-du-Prince-Édouard, nous avons produit des tables détaillées par année d'âge, pour les hommes et les femmes, ainsi que des tables par subdivisions de la première année de vie. Toutefois, en raison des faibles fréquences en cause, nous n'avons dressé que des tables abrégées comportant des groupes d'âges quinquennaux pour l'Île-du-Prince-Édouard.

Données

Pour construire ces tables, nous avons besoin des données suivantes, pour les hommes et les femmes séparément, et pour le Canada et les provinces:

Le nombre de décès par année d'âge chez les enfants de un à quatre ans et par groupe quinquennal chez ceux de cinq ans et plus, pour les années civiles 1985, 1986 et 1987.

Le nombre de décès chez les enfants de moins d'un an, par subdivision de la première année de vie, pour les années 1985, 1986 et 1987.

Le nombre de décès chez les enfants de un à quatre ans, selon l'année de naissance, pour les années 1985, 1986 et 1987.

La population de recensement par année d'âge, au 1^{er} juin 1986.

The estimated population by single years up to the age of four, for the years 1985, 1986 and 1987.

The number of births for the years 1984-1987.

Methodology

The methodology followed in constructing the 1985-1987 tables is the same as the one that was employed previously in producing the set of tables for the years 1980-1982 (see Nagnur, 1984(1)). A minor modification which was introduced in the previous set of tables, is the truncation of the upper bound of the detailed tables by fixing the last pivotal value to be incorporated at the age of 102. The same has been continued for this set.

Infant Tables

This is the fourth time that the sets of life tables for the sub-divisions of the first year of life have been produced for Canada and the provinces. As was the case with respect to 1980-1982 tables, the method described in detail by Monroe G. Sirken(1) was employed in constructing these tables. The intrinsic basis underlying the production of these tables is the assumption that a closed cohort of 100,000 live births is subject to the mortality rates of sub-divisions of a year of age, but for the first year of life only. Though these tables have been produced for Canada as well as the provinces, only Canadian tables have been included in this report; provincial tables could be obtained upon request.

Detailed Tables

The procedure employed in the construction of the detailed tables is basically the one given in the *United States Life Tables and Actuarial Tables* (1939-1941) by Thomas N.E. Greville(1). This was the same methodology that was employed for the

La population estimative par année d'âge jusqu'à l'âge de quatre ans, pour les années 1985, 1986 et 1987.

Le nombre de naissances pour les années 1984-1987.

Méthodologie

Pour construire les tables de 1985-1987, nous avons employé la même méthode que celle que nous avons utilisée auparavant pour produire la série des tables de 1980-1982 (voir Nagnur, 1984(1)). Tout comme pour l'ensemble précédent de tables, nous l'avons cependant modifiée légèrement de façon à réduire la limite supérieure des tables détaillées en fixant à 102 ans la dernière valeur "pivot". Nous avons procédé de la même façon pour cet ensemble.

Tables sur les enfants de moins d'un an

C'est la quatrième fois que nous publions les séries de tables de mortalité pour les subdivisions de la première année de vie pour le Canada et les provinces. Comme dans le cas des tables de 1980-1982, nous avons utilisé la méthode décrite en détail par Monroe G. Sirken(1). L'élaboration de ces tables repose sur l'hypothèse selon laquelle une cohorte fermée de 100,000 naissances vivantes affiche les taux de mortalité des subdivisions d'une année d'âge, mais pour la première année de vie seulement. Bien que ces tables aient été produites à la fois pour le Canada et les provinces, nous ne présentons ici que celles du Canada, on peut obtenir les tables provinciales sur demande.

Tables détaillées

La méthode employée pour l'établissement des tables détaillées est fondamentalement la même que celle qui figure dans le document *United States Life Tables and Actuarial Tables* (1939-1941), de Thomas N.E. Greville(1). Il s'agit de la même méthode que celle que nous avons utilisée

(1) Voir références à la fin du texte.

earlier sets of tables beginning with the years 1970-1972.

The principle values, nq_x s (the probability of dying within the span, from the beginning of age "x" to the beginning of age "x + n"), for the ages one to four were derived on the basis of the corresponding: (a) population as of June 1, 1985, 1986 and 1987; (b) the deaths for the calendar years 1985, 1986 and 1987; and (c) the births for the four calendar years 1984-1987 tabulated by year of birth.

The tables for age five and over were constructed by first obtaining the values of nq_x s calculated for the "pivotal" ages, such as 7, 12, 17 ... 92, at the middle of the traditional quinquennial age groups. The formula used to derive pivotal nq_x s was:

$$nq_x = \frac{nD_x}{n^P_x + 1/2 nD_x} = \frac{2 \cdot nD_x}{2 \cdot n^P_x + nD_x}$$

where

nD_x = average deaths for the three years 1985, 1986 and 1987, for the corresponding age groups

n^P_x = average population (as of June 1, 1986) for the corresponding period and age group.

On the basis of these "pivotal" nq_x values, other nq_x s were derived by the application of osculatory interpolation formulae for all integral values beginning five years of age and over.

Abridged Tables

Because of the smaller population and consequently of smaller frequencies, the detailed life tables for the province of Prince Edward Island could not meaningfully be constructed. Hence, following the procedure adopted with respect to 1970-1972 life

pour dresser les séries précédentes de tables pour les années 1970 à 1972 et les années suivantes.

Les valeurs principales nq_x s (probabilité de décès au cours de l'intervalle, à partir du début de l'âge "x" jusqu'au début de l'âge "x + n") pour les enfants de un à quatre ans ont été calculées en fonction: a) de la population correspondante au 1^{er} juin 1985, 1986 et 1987; b) des décès correspondants pour les années civiles 1985, 1986 et 1987; et c) des naissances correspondantes pour les quatre années civiles 1984-1987, totalisées par année de naissance.

Nous avons construit les tables portant sur les enfants de cinq ans et plus en obtenant d'abord les valeurs de nq_x s, calculées pour les âges "pivots", comme 7 ans, 12 ans, 17 ans ... 92 ans, au milieu des groupes d'âges quinquennaux traditionnels. Voici la formule utilisée pour calculer la valeur pivot nq_x s:

$$nq_x = \frac{nD_x}{n^P_x + 1/2 nD_x} = \frac{2 \cdot nD_x}{2 \cdot n^P_x + nD_x}$$

où

nD_x = nombre moyen de décès pour les trois années 1985, 1986 et 1987 dans les groupes d'âges correspondants

n^P_x = population moyenne (au 1^{er} juin 1986) pour la période et le groupe d'âges correspondant.

D'autres valeurs de nq_x s ont été calculées en fonction de ces valeurs "pivots" nq_x en appliquant des formules d'interpolation par osculation pour toutes les valeurs intégrales commençant à cinq ans et plus.

Tables abrégées

Nous n'avons pu construire d'une manière significative les tables de mortalité détaillées pour l'île-du-Prince-Édouard, car la population n'est pas assez nombreuse et les fréquences sont trop faibles. Nous avons donc élaboré des tables de mortalité abrégées distinctes pour les hommes

(1) See references at end of text.

(1) Voir références à la fin du texte.

tables, the abridged life tables separately for males and females, were constructed. The methodology has been explained in a technical paper by J. Silins and W. Zayachkowski.(1) The procedure and computer routine employed in deriving the values for 1985-1987 tables were exactly the same as was employed previously.

Population Undercoverage in the 1986 Census

The results of research conducted following the 1986 Census have indicated that the estimated rate of population undercoverage in the 1986 Census was somewhat higher than the estimated rate for the 1981 Census (see Statistics Canada, 1988(1)). In order to assess the effect that census undercoverage may have had on the life table values, two additional sets of life tables were prepared for 1985-87. In the first of these sets, the 1986 population counts have been weighted by the age-sex-specific estimated undercoverage rates that have been prepared for the Atlantic Region, Quebec, Ontario, Prairie Region and British Columbia. In the second set, the tables were prepared using post-censal population estimates for 1986 that are based on the 1981 Census. In both cases, the resulting impact on the life tables is minimal. Copies of these latter two sets of tables may be obtained on request from Health Division.

Explanation of Various Columns of Life Tables

Column I, age interval (x to $x + n$). The age interval shown is the interval between the two exact ages indicated or implied. For example, in case of the detailed life tables, the age "30" connotes the interval of one year between the 30th birthday and the 31st birthday; with respect to the abridged life table, the age group "40-45" connotes the interval between the 40th birthday and 45th birthday; with respect to the infant tables, the interval "4-5" days means the interval between the beginning of the 4th day to the beginning of the 5th day.

(1) See references at end of text.

et les femmes en employant la méthode adoptée pour dresser les tables de 1970-1972. Cette méthode est expliquée dans un document technique rédigé par J. Silins et W. Zayachkowski(1). La procédure et le programme informatique utilisés pour calculer ces valeurs dans les tables de 1985-1987 sont exactement les mêmes que ceux qui ont été utilisés auparavant.

Sous-dénombrement de la population dans le recensement de 1986

Les résultats de la recherche menée après le recensement de 1986 indiquent que le taux estimé de sous-dénombrement de la population au recensement de 1986 est un peu plus élevé que le taux estimé pour le recensement de 1981 (voir Statistique Canada, 1988(1)). Afin d'évaluer l'effet que le sous-dénombrement du recensement peut avoir eu sur les valeurs des tables de mortalité, deux séries supplémentaires de tables de mortalité ont été calculées pour 1985-1987. Dans la première de ces séries, les chiffres de population de 1986 ont été pondérés par les taux estimés de sous-dénombrement selon l'âge et le sexe qui avaient été calculés pour la région de l'Atlantique, le Québec, l'Ontario, les Prairies et la Colombie-Britannique. Dans la seconde série, les tables ont été calculées à l'aide des estimations postcensitaires de la population de 1986, qui se fondent sur le recensement de 1981. Dans les deux cas, l'impact sur les tables de mortalité est minime. On peut obtenir des exemplaires de ces deux séries de tables en s'adressant à la Division de la santé.

Explication des diverses colonnes des tables de mortalité

Colonne I, intervalle d'âge (x à $x + n$). L'intervalle d'âge représente l'intervalle entre deux âges exacts indiqués ou supposés. Par exemple, dans le cas des tables de mortalité détaillées, "30 ans" représente l'intervalle d'un an entre le 30^e anniversaire et le 31^e anniversaire; dans le cas de la table abrégée, le groupe d'âges "40-45 ans" représente l'intervalle entre le 40^e anniversaire et le 45^e anniversaire; en ce qui concerne les tables portant sur les enfants de moins d'un an, l'intervalle "4-5 jours" désigne l'intervalle entre le début du 4^e jour et le début du 5^e jour.

(1) Voir références à la fin du texte.

Column L, number surviving (l_x). This column represents the number of persons of the initial cohort of 100,000 births surviving to the exact age marking the beginning of each age interval. The progressive values of l_x could be derived by the successive application of ${}_np_x (= 1 - {}_nq_x)$ values to the remainder of the original cohort of 100,000 live births still alive at the beginning of each interval.

Column D, number dying (${}_nd_x$). This column shows the number dying in each successive age interval out of the initial cohort of 100,000 live births. This could be obtained by multiplying the corresponding l_x by the corresponding ${}_nq_x$. Thus ${}_nd_x = l_x \cdot {}_nq_x$.

Column P, proportion surviving (${}_np_x$). This column represents the proportion of the survivors of the initial cohort, who are alive at the beginning of the age-interval, will survive to the beginning of the next age interval. This is the complement of ${}_nq_x$ the proportion dying. i.e., ${}_np_x = 1 - {}_nq_x$ (or ${}_np_x + {}_nq_x = 1$).

Column Q, proportion dying (${}_nq_x$). This column represents the proportion of the initial cohort of 100,000 who are alive at the beginning of the corresponding age interval who will die before reaching the end of the age-interval. This is the most important column of the life table and is the basis for the entire table structure. This is also the initial column in the generation of a life table from which other columns are derived on the basis of inter-dependent relationships.

Column LL, stationary population (${}_nL_x$). If one assumes that the cohort of 100,000 persons is being born every year, and this continues for a long time, and that the proportion dying in each age-interval throughout their life span is fixed as determined by the values of ${}_nq_x$ s and it is further assumed that the deaths are evenly distributed over the range of age-interval, then the survivors of these successive cohorts constitute what could be viewed as a "stationary population". The situation of being stationary arises because the number living in any given age group for any year

Colonne L, nombre de survivants (l_x). Cette colonne représente le nombre de membres d'une cohorte de 100,000 naissances vivantes qui survivront jusqu'à l'âge exact marquant le début de chaque intervalle d'âge. Les valeurs progressives de l_x pourraient être calculées en appliquant successivement les valeurs de ${}_np_x (= 1 - {}_nq_x)$ au reste des membres de la cohorte de 100,000 naissances vivantes qui sont toujours vivants au début de chaque intervalle.

Colonne D, nombre de décès (${}_nd_x$). Cette colonne indique le nombre de décès survenant dans chaque intervalle d'âge successif à partir des 100,000 naissances vivantes du début. On pourrait obtenir cette valeur en multipliant la valeur correspondante de l_x par la valeur correspondante de ${}_nq_x$. Ainsi, ${}_nd_x = l_x \cdot {}_nq_x$.

Colonne P, probabilité de survie (${}_np_x$). Cette colonne représente la proportion de membres de la cohorte qui sont vivants au début de l'intervalle d'âge et qui survivront jusqu'au début du prochain intervalle d'âge. Cette valeur vient compléter la valeur ${}_nq_x$ (probabilité de décès). Ainsi, ${}_np_x = 1 - {}_nq_x$ (ou ${}_np_x + {}_nq_x = 1$).

Colonne Q, probabilité de décès (${}_nq_x$). Cette colonne représente la proportion de membres de la cohorte qui sont vivants au début de l'intervalle d'âge correspondant et qui mourront avant la fin de cet intervalle. C'est la colonne la plus importante de toute la table de mortalité et celle qui en constitue la base. C'est également la première colonne dressée lors de l'élaboration d'une table de mortalité et celle à partir de laquelle d'autres colonnes sont calculées en fonction de relations interdépendantes.

Colonne LL, population stationnaire (${}_nL_x$). Si l'on suppose qu'une cohorte de 100,000 personnes vient au monde chaque année et que cela se poursuit pendant longtemps, et que la proportion de membres qui meurent à chaque intervalle d'âge de la durée de vie de la cohorte est déterminée par les valeurs de ${}_nq_x$ s, et si l'on suppose de plus que les décès sont répartis également dans l'intervalle d'âge, alors les survivants de ces cohortes successives constituent ce que l'on pourrait appeler la "population stationnaire". On emploie le terme "stationnaire" parce que le nombre de personnes vivantes dans un groupe d'âges donné pour une année donnée ne changera

will not change and the number entering any age group will exactly equal the number leaving the group due to death or aging. The number of deaths each year equals the number of births which equals 100,000. In other words, the assumptions involved render the column of nL_x unchanging and thus stationary.

The derivation of the values of nL_x does vary at young ages due to the unevenness of the distribution of deaths over the range of the intervals - due to the higher risk of death in the earlier part of the interval and progressively reduced risk at the later part. Hence for ages one to four years, the following formulae were used:

$$L_1 = I_1 - (1 - f_x)$$

$${}_1L_x = I_x - (1 - f_x) {}_1d_x - \frac{1}{24} ({}_1d_{x-1} - {}_1d_{x+1}); \text{ for } x = 2, 3, 4$$

where, f_x the separation factor for age "x", represents the proportion of young children dying in a given age interval who have lived in excess of half the interval.

For ages five and over, it was considered sufficiently accurate to calculate nL_x using the approximate formulae:

$$nL_x = \frac{n}{2} (I_x + I_{x+1} + n)$$

Column I, cumulative stationary population (I_x). This column shows the cumulative total from below of the stationary population for all age groups up to and including the age interval indicated. Thus the I_x value at age "0" indicates the population at all ages "0" and above in the stationary population or the total stationary population:

$$I_x = nL_t$$

t = x to the end of table.

pas et le nombre de personnes entrant dans un groupe d'âges donné sera exactement égal au nombre de personnes qui quittent le groupe, soit parce qu'elles décèdent, soit parce qu'elles vieillissent. Le nombre de décès chaque année est égal au nombre de naissances, soit à 100,000. En d'autres termes, les hypothèses en cause font que la colonne de nL_x demeure inchangée, donc stationnaire.

Le calcul des valeurs de nL_x varie dans les plus bas âges en raison de l'inégalité de la répartition des décès dans les intervalles - vu les risques de décès plus élevés dans la première partie de l'intervalle et les risques progressivement moindres dans la seconde partie. Ainsi, pour les enfants de un à quatre ans, les formules suivantes ont été utilisées:

où, f_x facteur de séparation pour l'âge "x", représente la proportion de jeunes enfants qui meurent au cours d'un intervalle d'âge donnée et qui ont vécu pendant plus de la moitié de cet intervalle.

Pour les enfants de cinq ans et plus, nous avons jugé qu'il était suffisamment exact de calculer nL_x au moyen de la formule approximative:

$$nL_x = \frac{n}{2} (I_x + I_{x+1} + n)$$

Colonne I, population stationnaire cumulée (I_x). Cette colonne indique le total cumulé dans l'ordre ascendant de la population stationnaire pour tous les groupes d'âges allant jusqu'à l'intervalle d'âge indiqué, inclusivement. Ainsi, la valeur de I_x à l'âge "0" représente la population de tous les âges "0" et au-delà dans la population stationnaire ou la population stationnaire totale:

$$I_x = nL_t$$

t = x jusqu'à la fin de la table.

Column E, average remaining years of life (e_x^0). The expectation of life or the average remaining years of life at any given age is the mean number of years remaining to be lived by those surviving to that age on the basis of a given set of mortality rates. The values are obtained simply by dividing the T_x value by the corresponding l_x value i.e.,

$$e_x^0 = \frac{T_x}{l_x}$$

Limitations and Adjustments

An important variation in the procedure for the 1985-1987 cycle was the derivation of the pivotal values for the very old ages. The actual data were used up to age 95 - with the pivotal value at age 92. For the last pivotal values, instead of deriving the pivotal ${}_nq_x$ s by the conventional procedure, a third degree curve was fitted to the previous four pivotal values to obtain the successive ${}_nq_x$ s. The pivotal values thus derived progressively were terminated at the age of 102. Hence, the life table functions at ages beyond 95 should be interpreted with caution.

In this publication, for Canada as a whole, the life table functions are shown up to the age of 102. For the provinces, on the other hand, the tables were truncated at age 85 with an open ended category for the ages 85+.

The derivation of the functions for the open ended interval was as follows:

$$q_{85+} = 1.0$$

$$p_{85+} = 0.0$$

$$d_{85+} = l_{86} \text{ (column 'L' in the tables)}$$

$$L_{85+} = l_{86} \times E_{86} \text{ (column 'LL' in the tables)}$$

$$T_{85+} = L_{85+}$$

Colonne E, nombre moyen d'années de vie restantes (e_x^0). L'espérance de vie ou le nombre moyen d'années de vie restantes à tout âge donné représente le nombre moyen d'années qu'il reste à vivre à ceux qui vivent jusqu'à cet âge, en fonction d'un ensemble déterminé de taux de mortalité. Les valeurs sont obtenues simplement en divisant la valeur de T_x par la valeur correspondante de l_x . Ainsi,

$$e_x^0 = \frac{T_x}{l_x}$$

Limites et ajustements

Le calcul des valeurs pivots pour les âges très avancés constituait une variation importante de la méthode pour le cycle de 1985-1987. Les données réelles ont été utilisées jusqu'à l'âge de 95 ans - la valeur pivot étant 92 ans. Pour les dernières valeurs pivots, au lieu de calculer la valeur pivot ${}_nq_x$ s au moyen de la méthode conventionnelle, on a adapté une courbe de troisième degré aux quatre valeurs pivots précédentes pour obtenir la valeur successive ${}_nq_x$ s. Les valeurs pivots ainsi obtenues progressivement se terminaient à 102 ans. Donc, les fonctions des tables de mortalité pour les âges au delà de 95 ans doivent être interprétées avec prudence.

Dans la présente publication, pour l'ensemble du Canada, les fonctions des tables de mortalité figurent jusqu'à l'âge de 102 ans. Pour les provinces, d'autre part, les tables se terminent à 85 ans, une catégorie ouverte existant pour les 85 ans et plus.

Le calcul des fonctions de l'intervalle ouvert était le suivant:

$$q_{85+} = 1.0$$

$$p_{85+} = 0.0$$

$$d_{85+} = l_{86} \text{ (colonne "L" dans les tables)}$$

$$L_{85+} = l_{86} \times E_{86} \text{ (colonne "LL" dans les tables)}$$

$$T_{85+} = L_{85+}$$

All the ${}_n p_x$ and ${}_n q_x$ values were terminated at five significant digits as opposed to the seven digits customarily followed in the previous publications.

For ages one to four, the distribution of reported deaths, and consequently the life table functions, for certain provinces were found to be fluctuating and uneven. Hence adjustments and redistributions of deaths among the age-groups one to four was necessary. The redistribution was effected in the following manner: for both the Atlantic and Prairie provinces, the combined distribution of all deaths for all the provinces was employed. The overall effect of these redistributions, however, is expected to be minimal on the various functions of the respective tables.

Toutes les valeurs ${}_n p_x$ et ${}_n q_x$ se terminaient à cinq chiffres significatifs alors qu'elles se terminaient à sept chiffres dans les publications précédentes.

On a constaté que, pour les âges allant de un à quatre ans, la distribution des décès déclarés et, par conséquent, les fonctions des tables de mortalité pour certaines provinces fluctuaient et étaient inégales. C'est pourquoi il a fallu ajuster et redistribuer les décès parmi les enfants de un à quatre ans. La redistribution s'est faite de la façon suivante: en ce qui concerne et les provinces de l'Atlantique et les provinces des prairies, on a utilisé la distribution combinée de tous les décès pour toutes les provinces. L'effet global de ces redistributions sur les diverses fonctions des tables respectives devrait cependant être minime.
